1. Construct a diagram illustrating the dependence of electrode potentials (*vs.* NHE) on pH (Pourbaix diagram) for the following redox couples:

   a. $O_2 + e^- + H^+ \rightarrow HO_2^\bullet$

   b. $HO_2^\bullet + e^- + H^+ \rightarrow H_2O_2$

   c. $H_2O_2 + e^- + H^+ \rightarrow HO^\bullet + H_2O$

   d. $HO^\bullet + e^- + H^+ \rightarrow H_2O$

   e. $O_2 + 2e^- + 2H^+ \rightarrow H_2O_2$

   f. $H_2O_2 + 2e^- + 2H^+ \rightarrow 2H_2O$

   g. $O_2 + 4e^- + 4H^+ \rightarrow 2H_2O$

   In constructing your diagram, use the following standard potentials:

   | | |
   |---|---|
   | $O_2 + e^- \rightarrow O_2^{\bullet-}$ | $E° = -0.35$ V *vs.* NHE |
   | $HO_2^\bullet + e^- \rightarrow HO_2^-$ | $E° = 0.76$ V *vs.* NHE |
   | $H_2O_2 + e^- + H^+ \rightarrow HO^\bullet + H_2O$ | $E° = 0.80$ V *vs.* NHE |
   | $HO^\bullet + e^- + H^+ \rightarrow H_2O$ | $E° = 2.72$ V *vs.* NHE |
   and the following p$K_a$ values:

   | | |
   |---|---|
   | $HO_2^\bullet \rightarrow O_2^{\bullet-} + H^+$ | p$K_a$ = 4.8 |
   | $H_2O_2 \rightarrow HO_2^- + H^+$ | p$K_a$ = 11.62 |
   | $HO^\bullet \rightarrow O^{\bullet-} + H^+$ | p$K_a$ = 11.7 |
   | $H_2O \rightarrow HO^- + H^+$ | p$K_a$ = 14.0 |

   The standard state for potentials is 25 °C, concentrations of 1 molal (1 *m*), partial gas pressures of 100 kPa, and the activity of water is taken to be unity. For the purposes of your diagram, assume the following conditions:

   $pO_2 = 100$ kPa

   $[HO_2^\bullet] + [O_2^{\bullet-}] = 1\ m$

   $[H_2O_2] + [HO_2^-] = 1\ m$
   $[HO^\bullet] + [O^{\bullet-}] = 1\ m$

   Your plot should span the range from pH 0 to pH 14.

2. Using the data from your Pourbaix diagram give the electrode potentials for the redox couples *a-g* at the following pH values:

     a. pH 0          b. pH 7       c. pH 14

3. Using the data from your Pourbaix diagram determine the standard free energy change for the following reaction:

$$2HO^{\bullet} \rightleftharpoons H_2O_2$$

4. It should be clear from your Pourbaix diagram that the electrode potential for the four-electron, four-proton oxidation of water is substantially lower than those for some of the steps in the sequential one-electron oxidation of water to dioxygen. The stepwise oxidation of water, then, requires large overpotentials; these overpotentials can be reduced if the intermediates in the water oxidation sequence are bound to metal complexes as illustrated below. Define the potential for redox reaction *g* from question 1 (pH 7, 25 °C) to be equal to that for the oxygen evolving reaction ($E_{OER}$).

$$2H_2O + M(OH_2)_2^{n+}$$

$$E_d \uparrow\downarrow \qquad\qquad\qquad \nwarrow E_{OER}$$

$$2HO^{\bullet} + 2H^+ + 2e^- + M(OH_2)_2^{n+} \quad \overset{K_1}{\underset{\leftarrow}{\rightarrow}} \quad 2H^+ + 2e^- + M(OH)_2^{n+} + 2H_2O$$

$$\Delta G_1^{\circ} \uparrow\downarrow \qquad\qquad\qquad \downarrow\uparrow \Delta G^{\circ} = 0$$

$$H_2O_2 + 2H^+ + 2e^- + M(OH_2)_2^{n+} \quad \overset{K_2}{\underset{\leftarrow}{\rightarrow}} \quad 3H^+ + 2e^- + M(OH_2)(O_2H)^{(n-1)+} + H_2O$$

$$E_b \uparrow\downarrow \qquad\qquad\qquad \downarrow\uparrow E_{OER}$$

$$HO_2^{\bullet} + 3H^+ + 3e^- + M(OH_2)_2^{n+} \quad \overset{K_3}{\underset{\leftarrow}{\rightarrow}} \quad 3H^+ + 3e^- + M(OH_2)(O_2H)^{n+} + H_2O$$

$$E_a \uparrow\downarrow \qquad\qquad\qquad \downarrow\uparrow E_{OER}$$

$$O_2 + 4H^+ + 4e^- + M(OH_2)_2^{n+} \quad \overset{K_4}{\underset{\leftarrow}{\rightarrow}} \quad 4H^+ + 4e^- + M(OH_2)(O_2)^{n+} + H_2O$$

Use the data from your Pourbaix diagram and the answer from question 3 ($\Delta G_1^{\circ}$) to estimate values for the equilibrium constants for binding to a generic metal center ($M(OH_2)_2^{n+}$) of the intermediates in the water oxidation sequence, *i.e.*, $K_1$, $K_2$, $K_3$, and $K_4$.
